

## The Production of Health from a Historical Perspective

ECON 40447  
Bill Evans  
Fall 2009

1

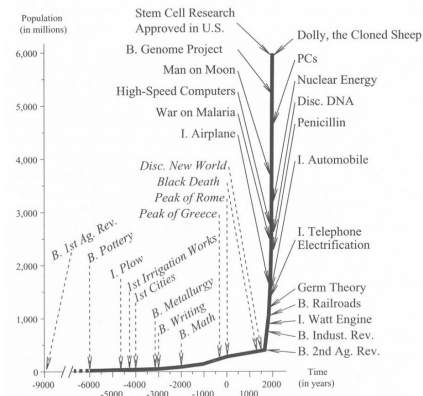

Figure 2.1 The Growth of World Population and Some Major Events in the History of Technology.

2

### Mortality changes from a historical perspective

- Surprisingly stable population over long period of history
- As we will see in a moment – driven by stable mortality rates
- World population
  - Time of Christ, 300 million
  - Vikings, 1000 years later, about the same
  - 1700, 600 million
  - Today, 6 billion

3

- $\text{Pop}(t)$  = population in year  $t$
- $\text{Deaths}(t)$ ,  $\text{Births}(t)$  similarly defined
- Dynamics for world
- $\text{Pop}(t+1) = \text{Pop}(t) + \text{births}(t) - \text{deaths}(t)$
- Dynamics for country
- $\text{Pop}(t+1) = \text{Pop}(t) + \text{births}(t) - \text{deaths}(t) + \text{netMig}(t)$

4

## Demographic transition

- As industrialization takes hold, countries move from a high death/birth era to one of lower birth/death rates
- Birth rates/death rates move in unison

5

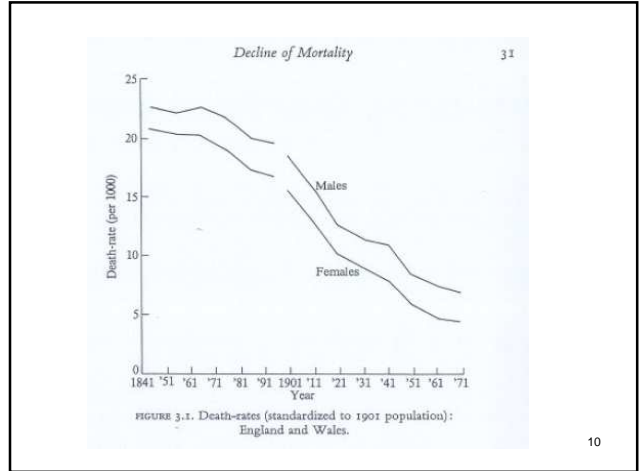

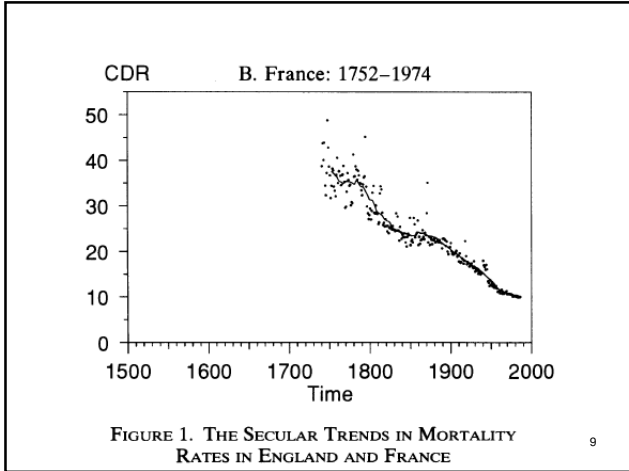

6

- $Pop(t+1) = Pop(t) + births(t) - deaths(t)$
- The rise in population must be driven by a reduction in mortality rates
- Historically, death rates have not wavered much til the end of the late 19<sup>th</sup> century
- What drove the big decline in death rates?

7

8

**McKeown**

- **Why the rapid increase in population (decline in mortality) in England/Wales?**
- **Key fact – most of the decline was due to a reduction in deaths from infectious diseases**
  - 74% are attributable to microorganisms

**Table 3.2 Reduction in Mortality England/Wales 1850-1971**

| • Conditions attributable:                       | • Percent of reduction |
|--|------------------------|
| • Airborne diseases                              | • 40%                  |
| • Water/food borne diseases                      | • 21%                  |
| • Other micro organisms                          | • 13%                  |
| • Conditions not attributable to micro-organisms | • 26%                  |

TABLE 3.3. Standardized death-rates (per million) from airborne diseases: England and Wales

|                                    | 1848-54 |      | 1971    |      | Percentage of reduction from all causes attributable to each disease |
|------------------------------------|---------|------|---------|------|--|
|                                    | 1848-54 | 1971 | 1848-54 | 1971 |  |
| Tuberculosis (respiratory)         | 2,901   | 13   | 17.5    | 17.5 | 17.5   |
| Bronchitis, pneumonia, influenza   | 2,239   | 603  | 9.9     | 9.9  | 9.9  |
| Whooping cough                     | 423     | 1    | 2.6     | 2.6  | 2.6  |
| Measles                            | 342     | 0    | 2.1     | 2.1  | 2.1  |
| Scarlet fever and diphtheria       | 1,016   | 0    | 6.2     | 6.2  | 6.2  |
| Smallpox                           | 263     | 0    | 1.6     | 1.6  | 1.6  |
| Infections of ear, pharynx, larynx | 75      | 2    | 0.4     | 0.4  | 0.4  |
| Total                              | 7,259   | 619  | 40.3    | 40.3 | 40.3   |

36 Determinants of Health

TABLE 3.4. Standardized death-rates (per million) from water- and food-borne diseases: England and Wales

|                                | 1848-54 |      | 1971    |      | Percentage of reduction from all causes attributable to each disease |
|--------------------------------|---------|------|---------|------|--|
|                                | 1848-54 | 1971 | 1848-54 | 1971 |  |
| Cholera, diarrhoea, dysentery  | 1,819   | 33   | 10.8    | 10.8 | 10.8   |
| Tuberculosis (non-respiratory) | 753     | 2    | 4.6     | 4.6  | 4.6  |
| Typhoid, typhus                | 990     | 0    | 6.0     | 6.0  | 6.0  |
| Total                          | 3,562   | 35   | 21.4    | 21.4 | 21.4   |

13

- Big question: why are people dying from infectious diseases at lower rates?
- McKeown suggests it is:
  - NOT medical care
  - NOT public health
- Question to consider: What evidence does McKeown give to argue against a public health interpretation???

14

FIGURE 8.1. Respiratory tuberculosis: mean annual death-rates (standardized to 1901 population): England and Wales.

FIGURE 8.12. Whooping cough: death rates of children under 15: England and Wales.

FIGURE 8.13. Whooping cough: mean annual notification rates of children under 15: England and Wales.

FIGURE 8.14. Measles: death rates of children under 15: England and Wales.

16

Fig. 5: Pneumonia & Influenza Deaths<sup>a</sup>

a - pneumonia and influenza deaths not reported separately prior to 1965. Influenza accounts for less than 3 percent of total deaths in this category in 1965.

Fig. 6: Tuberculosis Deaths

- **What might explain the decline in mortality?**
- **Decline in virulence of infection**
- **Why? Agricultural revolution**
  - Limited food supply through 1850 generated 'small' humans
  - People with limited diets cannot ward off infections
  - The growth in agriculture productivity allows humans to grow and be healthier
- **Evidence on McKeown?**

19

### Fogel

- **Nobel prize winning economist from Chicago**
- **Took McKeown's idea to heart and provided critical data**
- **At end of the 18<sup>th</sup> century, average height of adult in England/France was 5'4"**
- **Not much change throughout Europe until last half 19<sup>th</sup> century**
- **Height is an excellent predictor of disease incidence/mortality**
- **Height improved because of diet**

20

TABLE 1—ESTIMATED AVERAGE FINAL HEIGHTS OF MEN WHO REACHED MATURITY BETWEEN 1750 AND 1875 IN SIX EUROPEAN POPULATIONS, BY QUARTER CENTURIES

| Row | Date of maturity by century and quarter | Height (cm)   |        |        |        |         |         |
|-----|---|---------------|--------|--------|--------|---------|---------|
|     |   | Great Britain | Norway | Sweden | France | Denmark | Hungary |
| 1   | 18-III                                  | 165.9         | 163.9  | 168.1  | —      | —       | 168.7   |
| 2   | 18-IV                                   | 167.9         | —      | 166.7  | 163.0  | 165.7   | 165.8   |
| 3   | 19-I                                    | 168.0         | —      | 166.7  | 164.3  | 165.4   | 163.9   |
| 4   | 19-II                                   | 171.6         | —      | 168.0  | 165.2  | 166.8   | 164.2   |
| 5   | 19-III                                  | 169.3         | 168.6  | 169.5  | 165.6  | 165.3   | —       |
| 6   | 20-III                                  | 175.0         | 178.3  | 177.6  | 172.0  | 176.0   | 170.9   |

Sources: Fogel (1987 table 7) for all countries except France. For France, rows 3–5 were computed from M. A. von Meerton (1989) as amended by Weir (1993), with 0.9 cm added to allow for additional growth between age 20 and maturity (Benjamin A. Gould, 1869 pp. 104–5) (cf. Gerald C. Friedman, 1982 p. 510 [footnote 14]). The entry to row 2 is derived from a linear extrapolation of Meerton's data for 1815–1836 back to 1788, with 0.9 cm added for additional growth between age 20 and maturity. The entry in row 6 is from Fogel (1987 table 7).

165 cm = 65 inches (5'5")  
175 cm = 69 inches (5'9")

21

## Calories available for work

- **Basal metabolic rate**
  - Calories necessary to keep vital organs working
  - 4/5ths of minimum calories
  - Function of body size
- **Calories necessary to consume/digest food**
  - 1/5th of minimum necessary
- **Amount above these limits, calories available for work**
- **1800-2600 calories available for work today in US**
- **In 1700 England, 1/3 to 1/4 of the calories that are available today**

22

Table 1.2 Secular Trends in the Daily Caloric Supply in France and Great Britain, 1700–1989 (calories per capita)

| Year    | France | Great Britain |
|---------|--------|---------------|
| 1700    |        | 2,095         |
| 1705    | 1,657  |               |
| 1750    |        | 2,168         |
| 1785    | 1,848  |               |
| 1800    |        | 2,237         |
| 1803–12 | 1,846  |               |
| 1845–54 | 2,480  |               |
| 1850    |        | 2,362         |
| 1909–13 |        | 2,857         |
| 1935–39 | 2,975  |               |
| 1954–55 | 2,783  | 3,231         |
| 1961    |        | 3,170         |
| 1965    | 3,355  | 3,304         |
| 1989    | 3,465  | 3,149         |

Table 1.3 A Comparison of Energy Available for Work Daily per Consuming Unit in France, England and Wales, and the United States, 1700–1994 (in kcal)

| Year | (1)<br>France | (2)<br>England and Wales | (3)<br>United States |
|------|---------------|--------------------------|----------------------|
| 1700 |               |                          | 2,313 <sup>a</sup>   |
| 1705 | 439           |                          |                      |
| 1750 |               | 720                      |                      |
| 1785 | 600           |                          |                      |
| 1800 |               | 858                      |                      |
| 1840 |               |                          | 1,810                |
| 1850 |               | 1,014                    |                      |
| 1870 | 1,671         |                          |                      |
| 1880 |               |                          | 2,709                |
| 1944 |               |                          | 2,282                |
| 1975 | 2,136         |                          |                      |
| 1980 |               | 1,793                    |                      |
| 1994 |               |                          | 2,620                |

<sup>a</sup> Prerevolutionary Virginia.

24

### Interesting facts

- Caloric intake in early 18<sup>th</sup> century France similar to 1965 Rwanda, the most malnourished country on the planet at that time
- During 18<sup>th</sup> century England, 50-75% of income went to food
- Caloric consumption in 1885 England similar to modern day India

25

### What is BMI?

- Body mass index
- weight in kg/Height in meters squared
  - BMI < 20 underweight
  - BMI > 25 overweight
  - BMI > 30 obese
- To calculate BMI w/ inches/pounds
  - 703\* pounds/inches squared
  - 5'9" and 165 pounds, BMI of 24.3

26

Figure 2.3 Comparison of Relative Mortality Risk by BMI among Men 50 Years of Age, Union Army Veterans around 1900 and Modern Norwegians.

Relative risk defined on next page

27

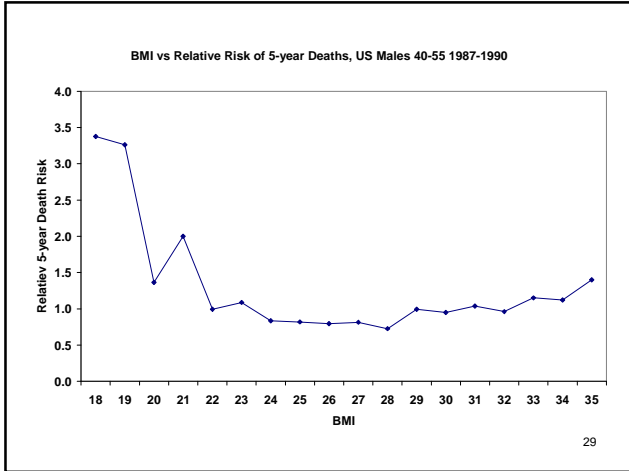

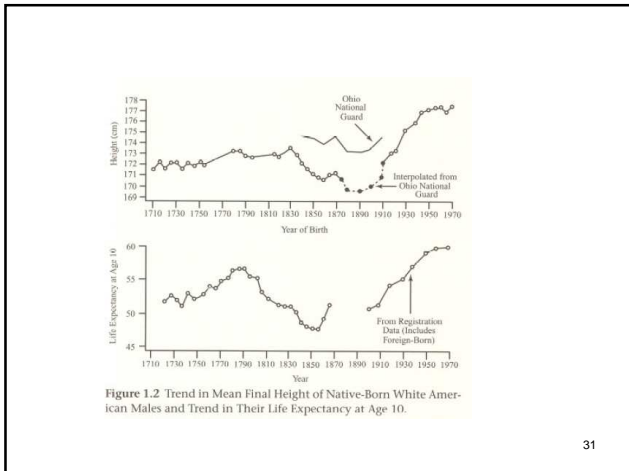

Figure 2.2 Relative Mortality Risk among Union Army Veterans and among Modern Norwegian Males.

Note: A relative risk of 1.0 means that the risk at that height was equal to the average risk of death in the entire population of males of the specified ages. Also note that the tallest data point, in both the Norwegian and Union Army cases, is not statistically significant.

28

- Look at the next two graphs, and consider the following questions:
- What trends in the graphs are 'good' for Fogel's story
- What trends in the graphs are not so good for his hypothesis.

- ### Slight problem for Fogel Theory
- Bones of exhumed remains can identify height
  - Linear relationship between length of femur and height
  - Need to know sex of skeleton
- Whites: Height = 61.61 + 2.38 FL, N = 710, SEE = 3.27  
Blacks: Height = 70.35 + 2.11 FL, N = 80, SEE = 3.94,

- **Need to know that the person stopped growing, identified by the fusion of certain bones**
- **Femur makes up ¼ of adult height – more in taller people**
- **U-shaped pattern over time, low point 1450-1750**

33

**Table 1** Average heights in northern Europe estimated from adult male skeletons

| Era               | Place   | Average height (cm) | Sample size | Source               |

| 18–19th centuries | Britain | 170.3              | 211   | Molleson and Cox 1993 |

35

### Why health gains during middle ages?

- **Favorable weather...increases crop yields**
  - Temps 2° C warmer 900-1300
  - Extend growing season by 3-4 weeks/year
- **Little exposure to infectious/communicable diseases**
  - Smaller cities (London had <40K people)
  - Little trade between countries to spread
- **These trends change after 1200**
  - little ice age
  - Increase urbanization

36

### What about the role of public health?

- **McKeown dismissed the importance of public health**
  - Time period when there has been a big movement from more rural to urban population
  - Infections should have been more prevalent due to close proximity in people (TB etc)
- **Most persistent criticism of McKeown, he understates value of public health**
  - Sanitation
  - Water supply

37

### Cutler and Miller

- **Consider the role of public health via clean water and sanitation at turn of century**
- **Tell very different story – large role for public health campaigns**
  - Effective at reducing infectious diseases
  - High rate of return

38

Table 1. Percentage of Deaths, by Cause, in Major Cities

| Cause of Death                | 1900 | 1936 |
|-------------------------------|------|------|
| Major Infectious Diseases     | 39.3 | 17.9 |
| Tuberculosis                  | 11.1 | 5.3  |
| Pneumonia                     | 9.6  | 9.3  |
| Diarrhea and enteritis        | 7.0  | N/A  |
| Typhoid fever                 | 2.4  | 0.1  |
| Meningitis                    | 2.4  | 0.3  |
| Malaria                       | 1.2  | 0.1  |
| Smallpox                      | 0.7  | 0.0  |
| Influenza                     | 0.7  | 1.3  |
| Childhood Infectious Diseases | 4.2  | 0.5  |
| Measles                       | 0.7  | 0.0  |
| Scarlet fever                 | 0.5  | 0.1  |
| Whooping cough                | 0.6  | 0.2  |
| Diphtheria and croup          | 2.3  | 0.1  |

Note: All percentages are shares of total mortality.

Source: U.S. Census Bureau's Mortality Statistics, 1900 and 1936.

In 2006, deaths from infectious diseases represented < 3% of all deaths

45

### Measure of financial effectiveness

- **Benefits of a program:** measured in lives
- **Costs:** measured in dollars
- **How does one compare outcomes across projects?**
- **Cost/life saved**
- **Hold denominator constant, lower values mean larger bang per buck**

46

Table 10. Social Rates of Return

|  | Point Estimate | 95% CI Low | 95% CI High |
|--|----------------|------------|-------------|
| % Mortality Reduction Due to Clean Water         | 0.1326         | 0.0373     | 0.2280      |
| 1915 Mortality Reduction per 100,000 Population  | 208            | 58         | 357         |
| 1915 Deaths Averted                              | 1,484          | 418        | 2,551       |
| 1915 Person-Years Saved                          | 57,922         | 16,301     | 99,543      |
| 1915 Annual Benefits in Millions of 2003 Dollars | 679            | 191        | 1,167       |
| 1915 Annual Costs in Millions of 2003 Dollars    | 29             |            |             |
| Social Rate of Return                            | 23.1           | 7.1        | 40.1        |
| Cost per Person-Year Saved in 2003 Dollars       | 500            | 1,775      | 291         |

47

### Comparison

- **Review of 587 “cost per life year saved” estimates**
- **Median was about \$80K**
- **Subgroup medians**
  - Medical, \$38K
  - Injury prevention \$96K
  - Toxin control, \$5.6 million

48

### Example cost per life year saved

- Smoke detectors           \$60K
- Pneumonia vaccine       \$28K
- ARVs for HIV             \$50K
- CABG                       \$250K
- Child restraints          \$1.5 Million
- State NOx rues           \$8.3 million
- Methylene chloride      \$12.7 million
- Benzene control rubber plants   \$40Bil

49

### Mortality this century

- Two halves
  - Decline in infant deaths (1/2 half)
  - Conquering cardiac disease
- Tremendous changes in aggregate statistics

50

Fig. 1: All cause mortality<sup>a</sup>

<sup>a</sup> - Death rates shown are adjusted to standard population of U.S. in 1940

Fig. 2: Life Expectancy at Birth

52

FIGURE 1. Infant mortality rate,\* by year — United States, 1915–1997

\*Per 1000 live births.

53

FIGURE 2. Maternal mortality rate,\* by year — United States, 1900–1997

\*Per 100,000 live births.

54

### Infant Mortality, 2002

55

### Terms

- **Mortality**
  - Neonatal < 28 days
  - Infant < 1 year
- **LBW < 2500 grams**
- **Very LBW < 1500 grams**
- **Preterm < 37 weeks**

56

### What causes big changes in life expectancy?

- Most deaths are to the elderly
- But, when an infant dies, you add a small number to the numerator in a life expectancy calculation
- Big changes will be generated by
  - Changes in the infant mortality rate
  - Changes in mortality for the elderly which are a large fraction of deaths

57

### Distribution of Deaths by Age

| • Age | Fraction of deaths | • Age | Fraction of deaths |
|-------|--------------------|-------|--------------------|
| <1    | 1.1%               | 55-64 | 10.4%              |
| 1-14  | 0.5%               | 65-74 | 17.3%              |
| 15-24 | 1.4%               | 75-84 | 28.9%              |
| 25-34 | 1.7%               | 85+   | 27.9%              |
| 35-44 | 3.7%               |       |                    |
| 45-54 | 7.1%               |       |                    |

74.1% of deaths are to people aged 65+

58

### Numeric Example

- Population with 100 people
- 10% die at age 1
  - ~ the 1900 infant mortality rate)
- If they survive, they live to age 75
- Life expectancy =  $(.1)(1) + (.9)(75) = 67.6$
  
- Suppose infant mortality rates drops to 1%
  - ~ the 1980 Infant mortality rate
- Life expectancy =  $(0.01)(1) + (.99)(75) = 74.3$

59

- What is the corresponding change in life expectancy necessary for the same type of change

$$(0.1)(1) + (.9)(81.4) = 74.3$$

60

Table 1: Contributions to Life Expectancy at Birth

| Change in Life Expectancy at Birth | 1900-40 | 1940-60 | 1960-90 |
|------------------------------------|---------|---------|---------|
| Total change                       | 15.9    | 6.4     | 5.1     |
| Change attributable to:            |         |         |         |
| Infant mortality (<1)              | 4.7     | 1.4     | 1.2     |
| Child mortality (1-14)             | 4.4     | 0.7     | 0.3     |
| Young adult mortality (15-44)      | 3.6     | 1.6     | 0.3     |
| Older adult mortality (45-64)      | 1.0     | 1.1     | 1.4     |
| Elderly mortality (65+)            | 0.4     | 1.2     | 1.8     |
| Covariance terms                   | 1.8     | 0.4     | 0.1     |

Note: The text describes the decomposition.

57% of decline  
In ½ 40 yrs  
Due to child/infant  
Health

62% due to changes  
In older adults

61

Figure 3: Mortality From Infectious Disease and Cardiovascular Disease, US 1900-2000

62

## Improvements in heart attack treatment

- In 1950s, standard treatment was bed rest
  - Medical textbook in the 1950s, “..bed rest for at least 6 weeks should be planned...”
  - Today we know bed rest is counter productive
- Now, right after heart attack
  - Patient is administered blood thinners (aspirin, heparin)
  - Beta blockers to make heart work more efficiently
  - Thrombolytics to dissolve clots

63

- Variety of surgical procedures to deal with blockages
  - Cardiac catheterization (detects extent of blockage)
  - CABG (coronary artery bypass surgery)
  - Angioplasty (balloon inserted into blocked artery and expanded to reduce clot)
  - Stents can be inserted to maintain bloodflow

64

**EXHIBIT 2**  
**Changes in The Surgical Treatment Of Heart Attacks, 1984-1998**

**SOURCE:** Authors' analysis of Medicare claims records for all elderly patients with a heart attack.  
**NOTES:** Procedure use is within ninety days of the initial admission for the heart attack. See references in text for more detail.
